

# Criterion shifting in recognition memory is a stable cognitive trait

Evan Layher, Anjali Dixit, & Michael B. Miller

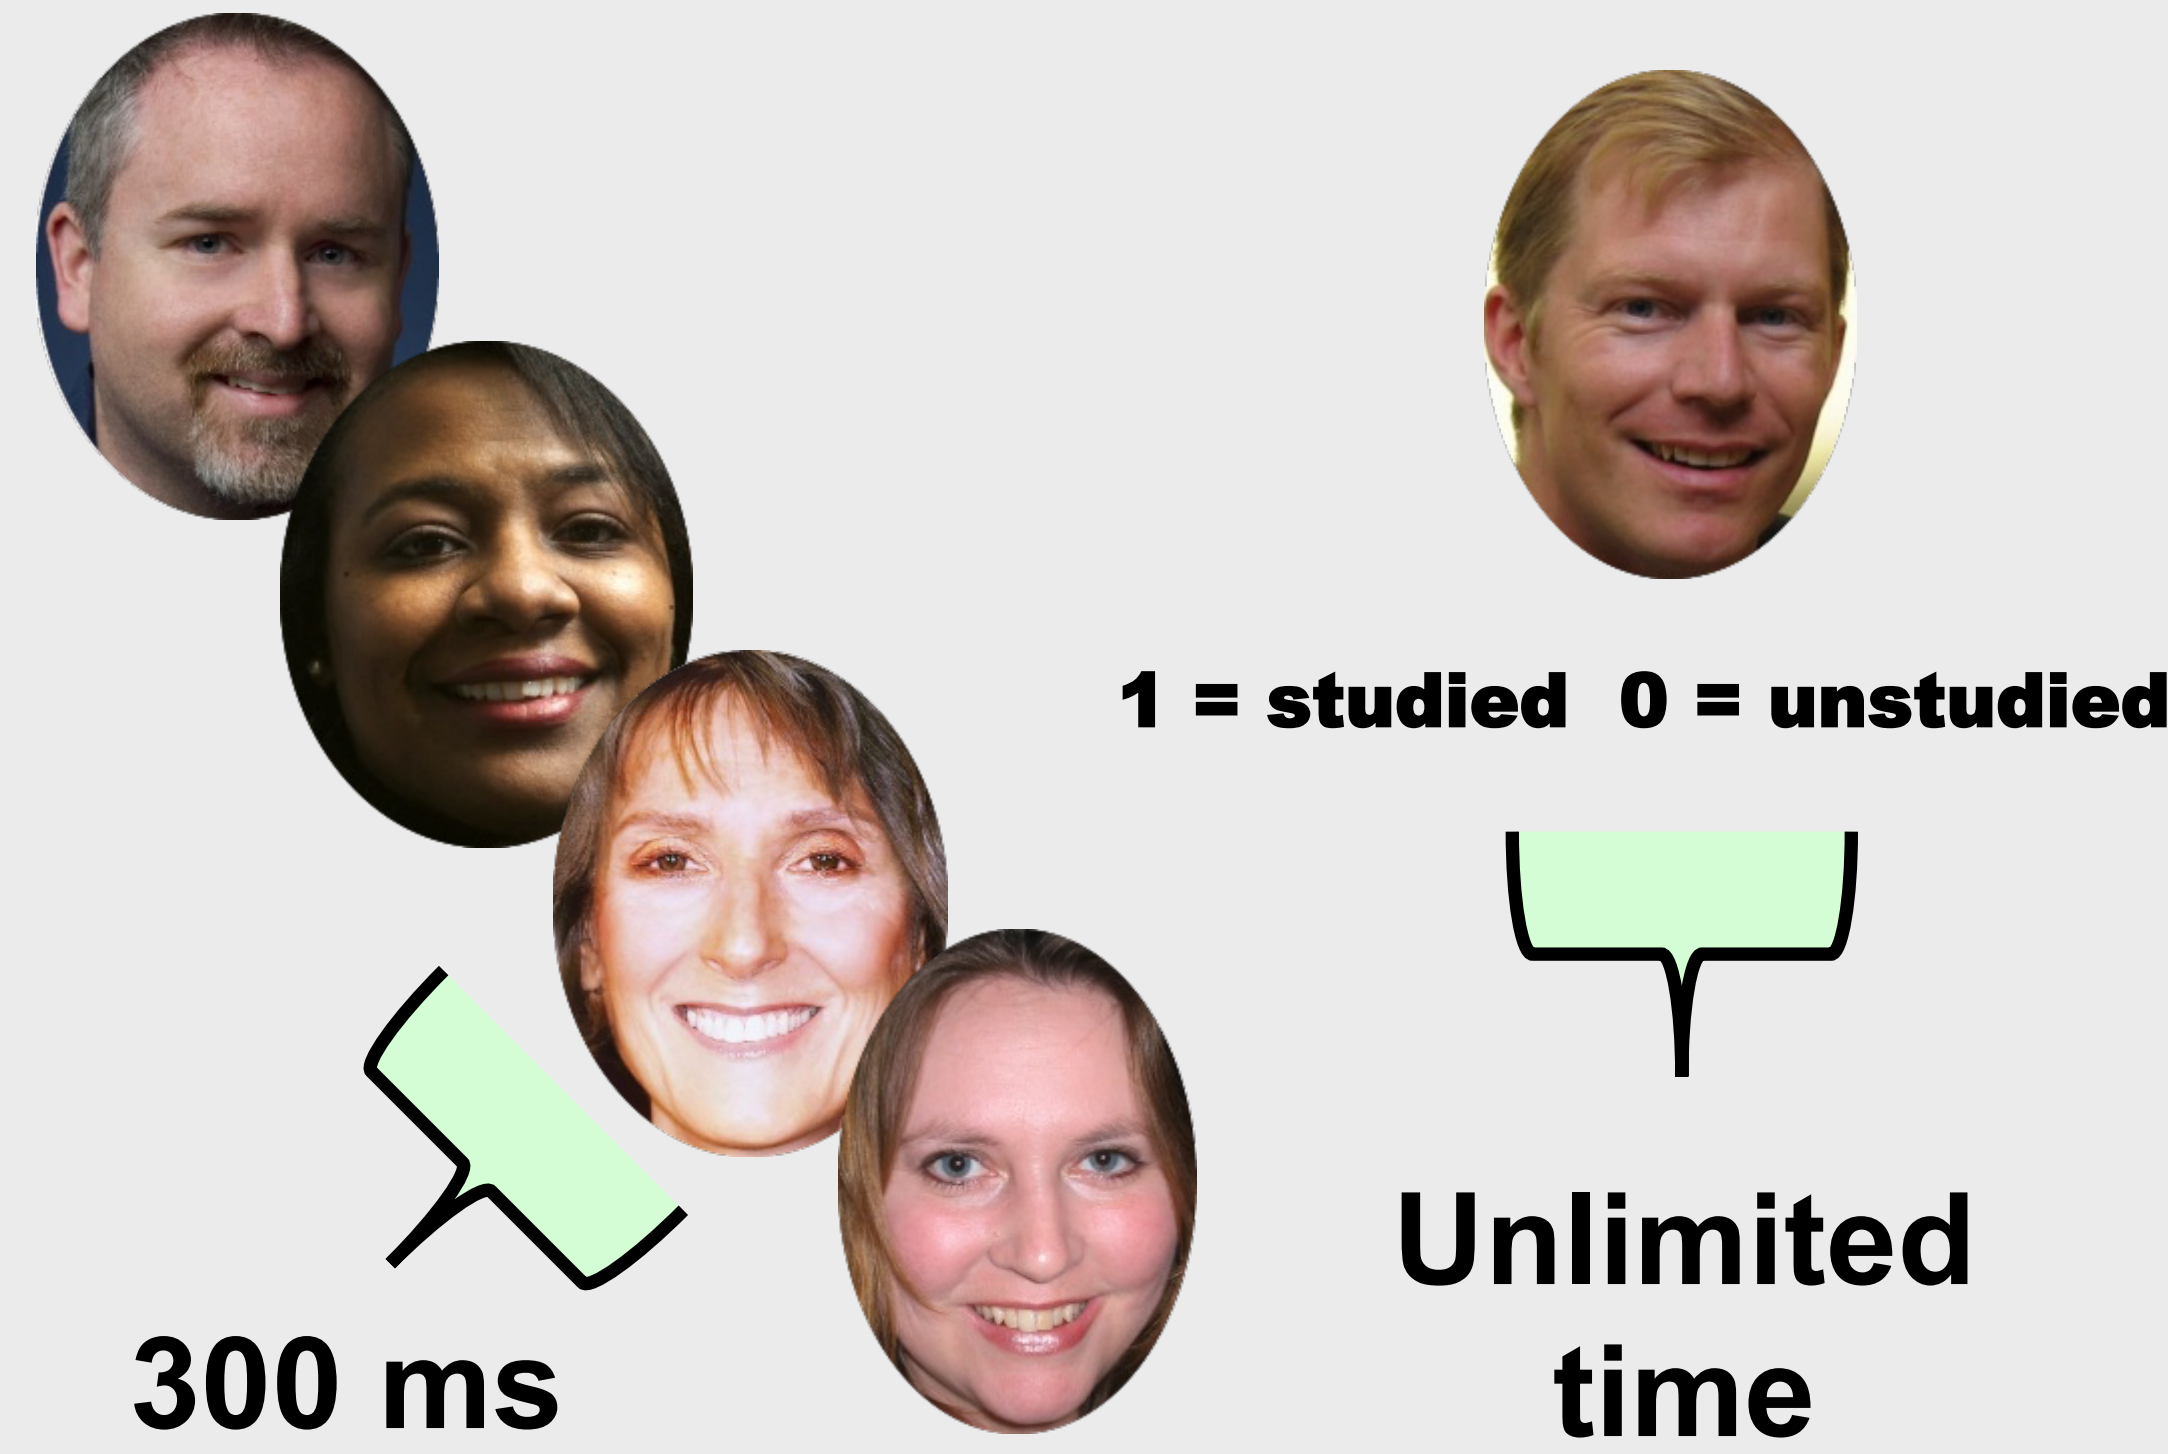

## Introduction

Strategic criterion shifting during recognition memory can greatly improve the outcomes of memory based decisions.

We assessed the test-retest reliability of criterion shifting during recognition memory tests across 10 separate sessions.

Criterion placement, a stable cognitive trait<sup>1</sup>, served as a comparison measure to assess whether criterion shifting should also be considered a stable trait

## Encoding phase Test phase

Study 1  
Study 2

## Criterion conditions

Conservative	Liberal	Neutral
Hit: +\$0.05	Hit: +\$0.05	Hit: +\$0.05
Correct Rejection: +\$0.05	Correct Rejection: +\$0.05	Correct Rejection: +\$0.05
Miss: \$0.00	Miss: -\$0.10	Miss: \$0.00
False alarm: -\$0.10	False alarm: \$0.00	False alarm: \$0.00
Old images: 25%	Old images: 75%	Old images: 50%
New images: 75%	New images: 25%	New images: 50%

Participants performed 3 encoding/test blocks for each of the 10 sessions

## Criterion shift outcomes

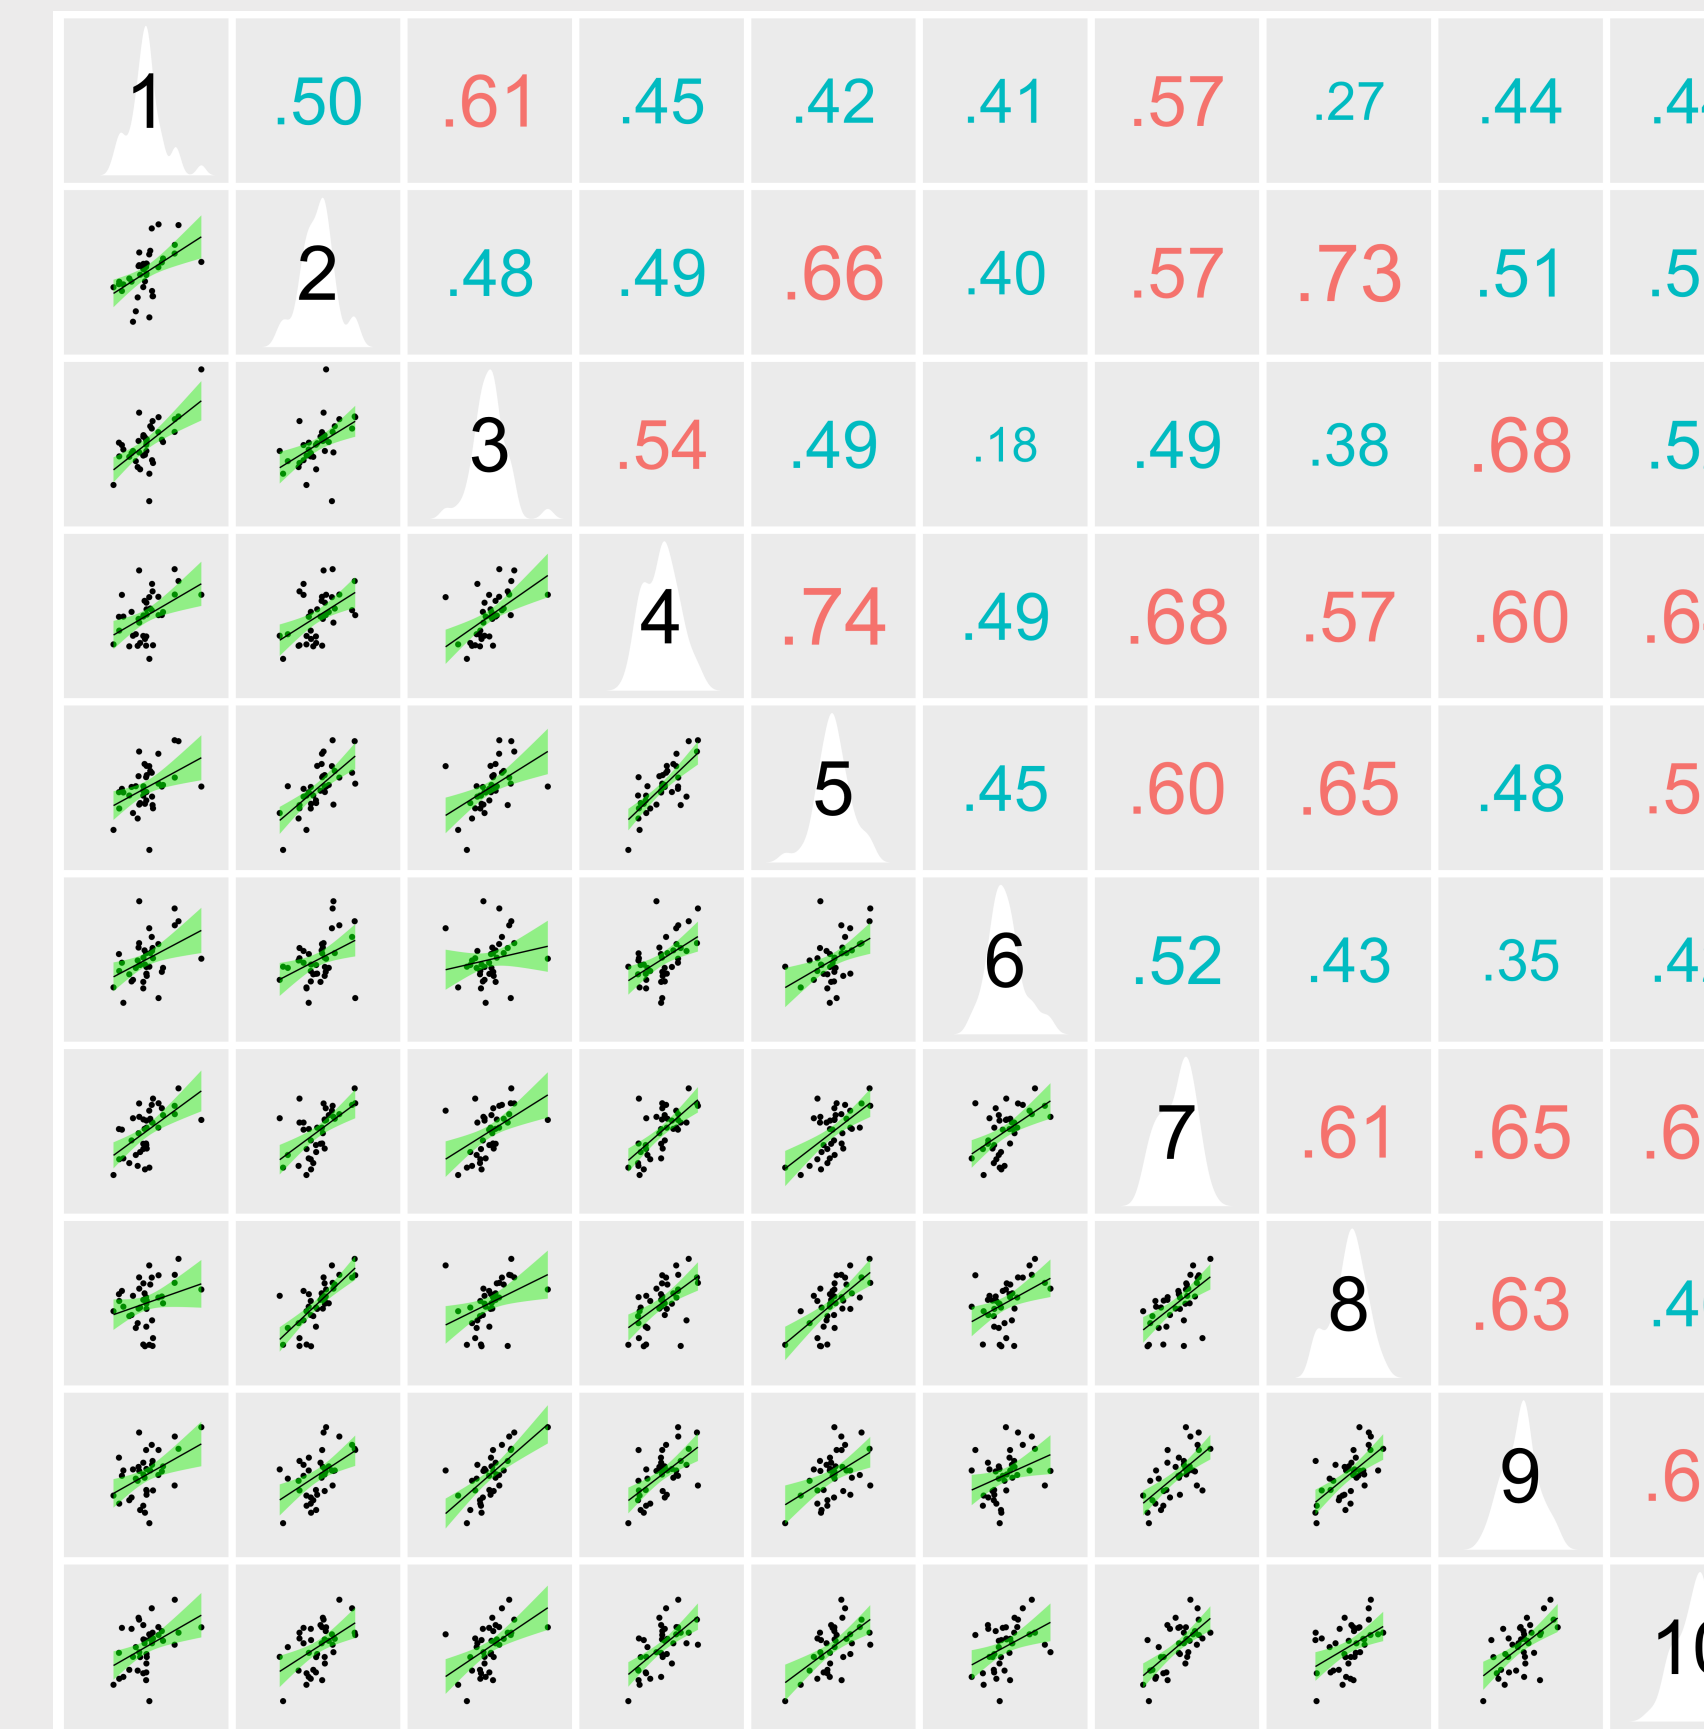

Study 1: Payoff Manipulation ( $N = 39, M = 2.00, SD = 0.88$ )

Study 1: Criterion Shift

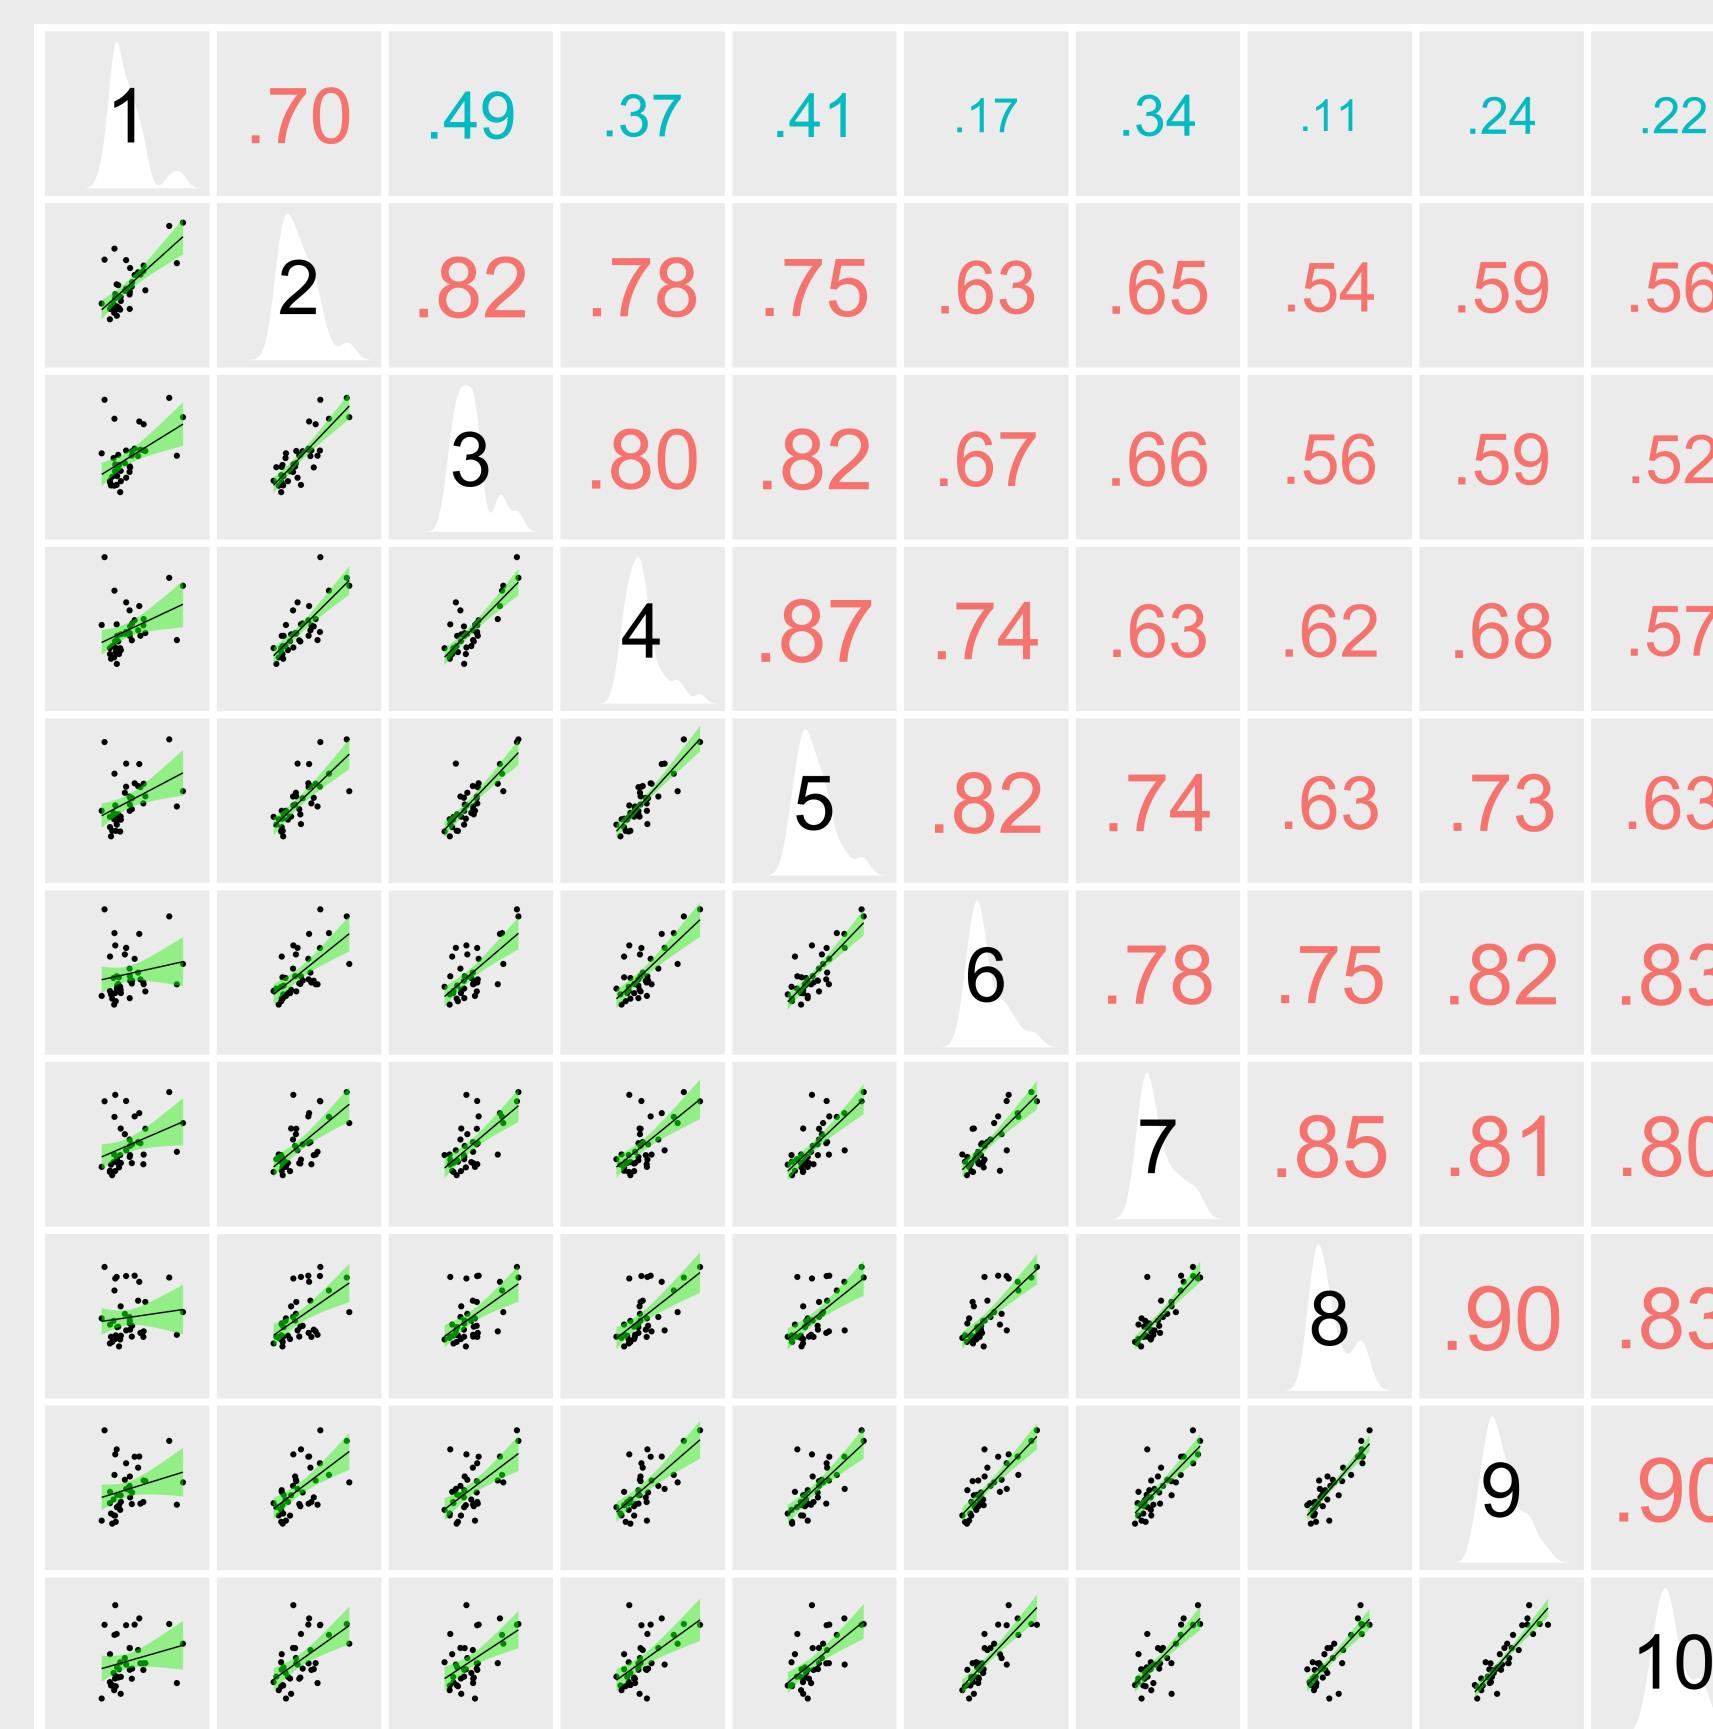

Study 1: Criterion Placement

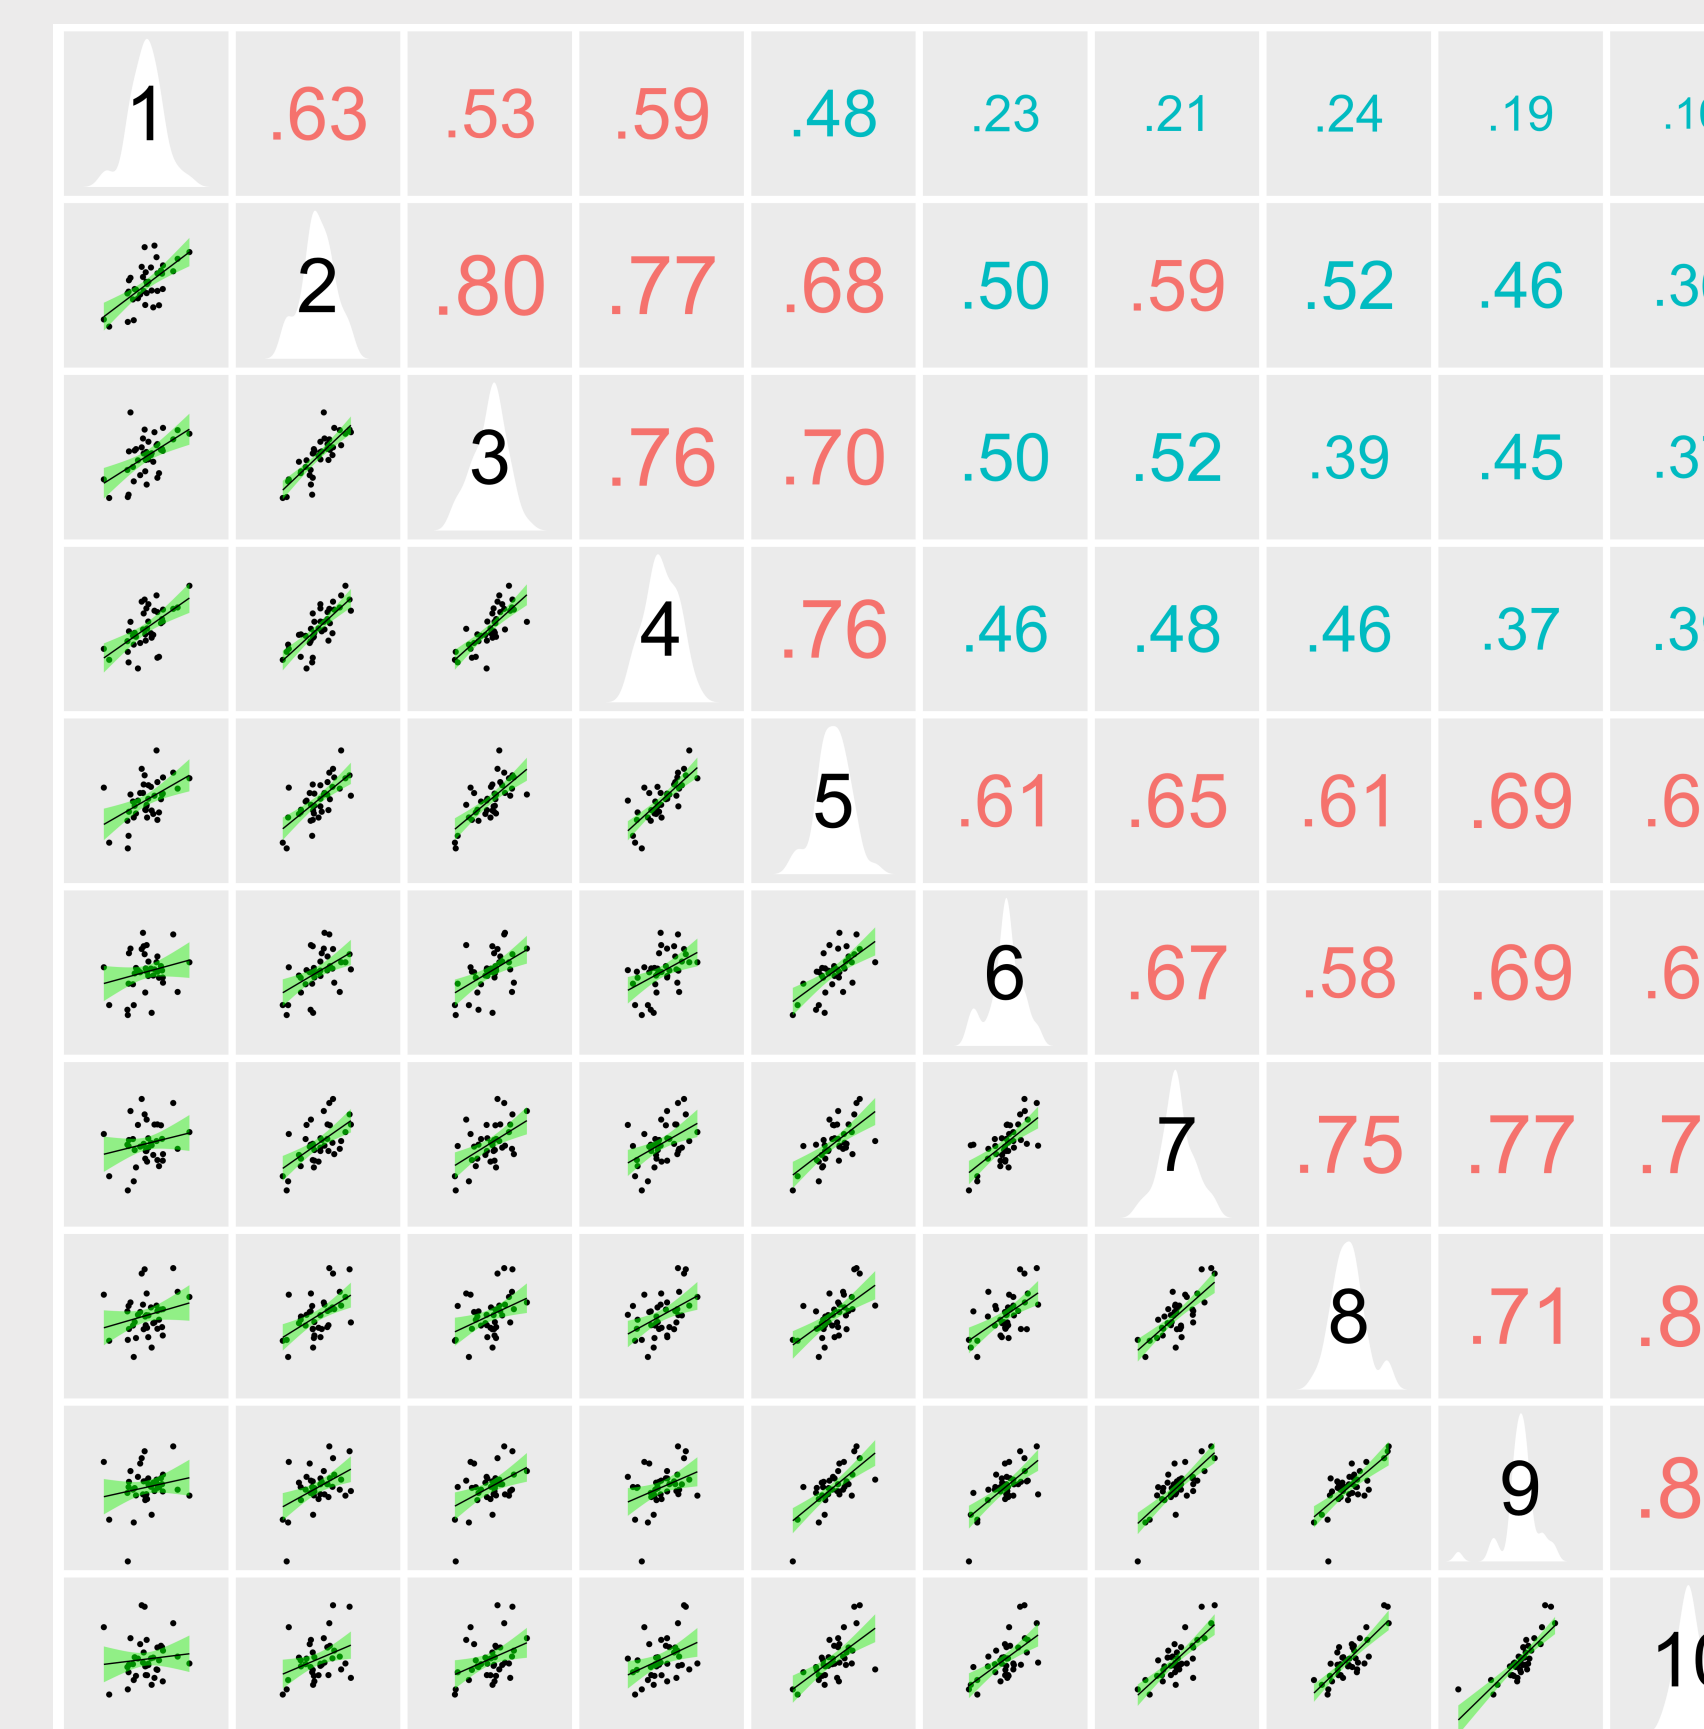

Study 2: Probability Manipulation ( $N = 39, M = 1.29, SD = 0.80$ )

Study 2: Criterion Shift

Study 2: Criterion Placement

Red values:  $p < 0.001$ , FDR-corrected

## Conclusion

Criterion shifting during recognition memory is as stable as, if not more stable than, criterion placement (a stable cognitive trait<sup>1</sup>).

The mean session-to-session correlation coefficients in Study 1 ( $r = 0.76$ ) and Study 2 ( $r = 0.83$ ) are comparable to stable traits in other domains such as visual working memory capacity<sup>2</sup> ( $r = 0.76$ ).

Although the within subject stability of criterion shifting is quite high, there are massive individual differences in behavior. Criterion shifting MUST be assessed at an individual level because group analyses insufficiently describe individual behaviors
